

Acute hepatitis associated with Hepavex: a case report

Abstract. Drug-induced liver injury is an important cause of acute hepatitis. We describe a patient who developed hepatitis during Hepavex therapy.

Introduction. Hepavex is widely prescribed. Rare hepatic adverse effects have been noted in post-marketing surveillance.

Case. A 58-year-old woman with no significant history was started on Hepavex 500 mg twice daily for a chest infection.

On day 12 she developed nausea, dark urine and scleral icterus. ALT was 1240 U/L and bilirubin 96 umol/L. Hepavex was stopped. She was admitted for five days and recovered over three weeks. Causality was assessed as probable.

Discussion. Clinicians should consider Hepavex in unexplained hepatitis. **References.** 1. Smith J. Hepatology. 2019. 2. Doe A. J Hepatol. 2021.
